Yasmini ECM for Blender

Version 1.0.0 · github.com/Robelugo/YasminiECM

Easy Color Management, Photoshop-style. Pick what your project is for and Yasmini ECM sets up everything else: display, view transform, look, working space, output format, and the color space of every texture.

Render Properties panel

Install

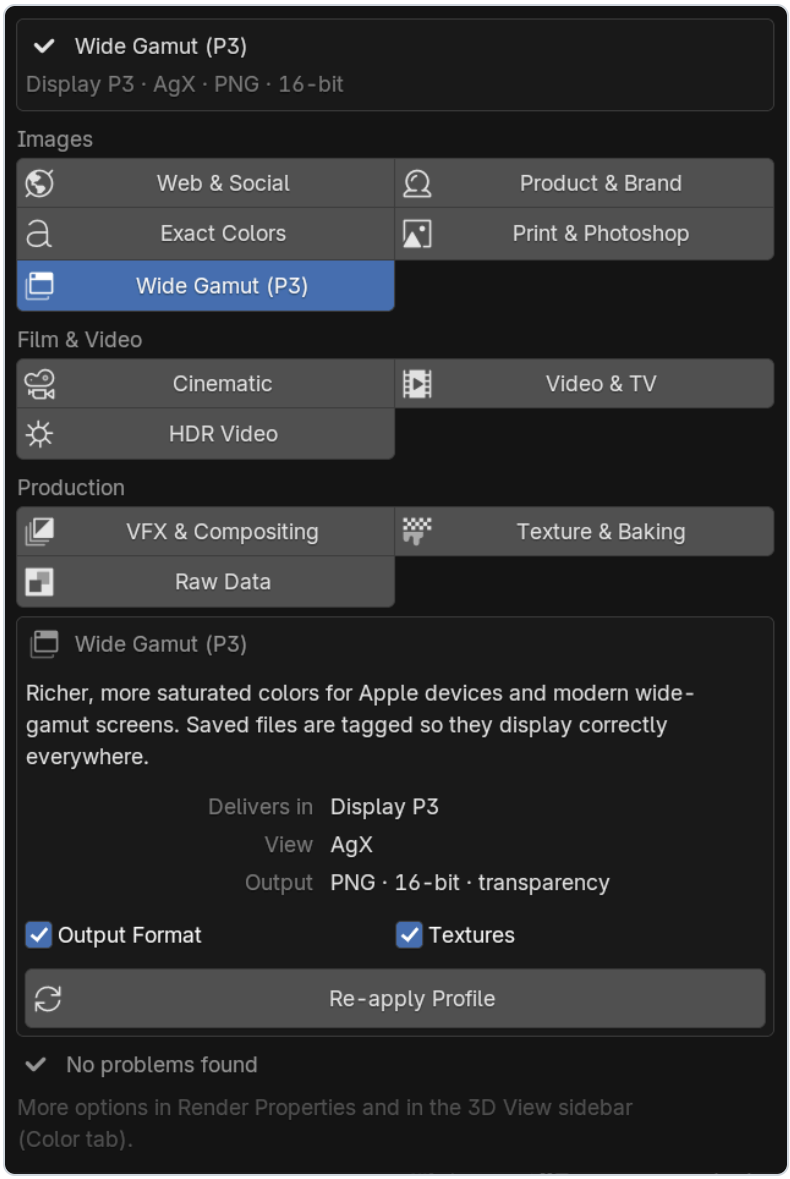

1. Download `yasmini_ecm-1.0.0.zip` from the latest release. Don't unzip it.
2. In Blender, open **Edit › Preferences › Get Extensions**.
3. In the drop-down at the top right, choose **Install from Disk…** and pick the zip.

Requires Blender 4.2 or newer. Tested on 4.4, 4.5, 5.1 and 5.2.

Use it

1. Open **Render Properties › Yasmini ECM**, the **Color** tab in the 3D View sidebar (press N), or click the profile name at the bottom right of the window.
2. Click what the project is for. The box below explains what that profile sets up.
3. Press **Apply Profile**.

That's it. The status bar shows the profile, like Photoshop's document profile, and the Health Check tells you, in plain language, if something drifts or looks wrong.

Status bar popover

The profiles

Profile	Delivers in	View	Output	Best for
Web & Social	sRGB	AgX	PNG 8-bit	websites, social media, client previews
Product & Brand	sRGB	Khronos PBR Neutral	PNG 8-bit	product shots, e-commerce, packaging
Exact Colors	sRGB	Standard	PNG 8-bit	logos, UI, motion graphics, toon shading
Print & Photoshop	sRGB	AgX	TIFF 16-bit	print, retouching in Photoshop
Wide Gamut (P3)	Display P3	AgX	PNG 16-bit	iPhone, iPad and Mac, modern phones
Cinematic	sRGB	AgX, Medium High Contrast	PNG 16-bit frames	animation, short films
Video & TV	Rec.709 (BT.1886)	AgX	H.264 MP4	TV, Resolve, Premiere
HDR Video	Rec.2100 PQ	AgX HDR 1000 nits	PNG 16-bit frames	HDR TVs, YouTube HDR (Blender 5+)
VFX & Compositing	sRGB	ACES 2.0 (Blender 5+) or AgX	Multilayer EXR	Nuke, Fusion, Resolve
Texture & Baking	sRGB	Standard	PNG 8-bit	texture painting, baking, game assets
Raw Data	sRGB	Raw	EXR 32-bit	depth and normal passes, masks, datasets

On Blender 5 and newer, **VFX & Compositing** also switches the file's working space to ACEScg. Blender converts existing colors, so nothing changes visually.

Applying a profile keeps your exposure and gamma tweaks. Only Exact Colors, Texture & Baking and Raw Data reset them, because those profiles promise a 1:1 result.

If a setting isn't available (an older Blender, or a studio OCIO config), the closest option is used and Yasmini ECM tells you which.

Textures

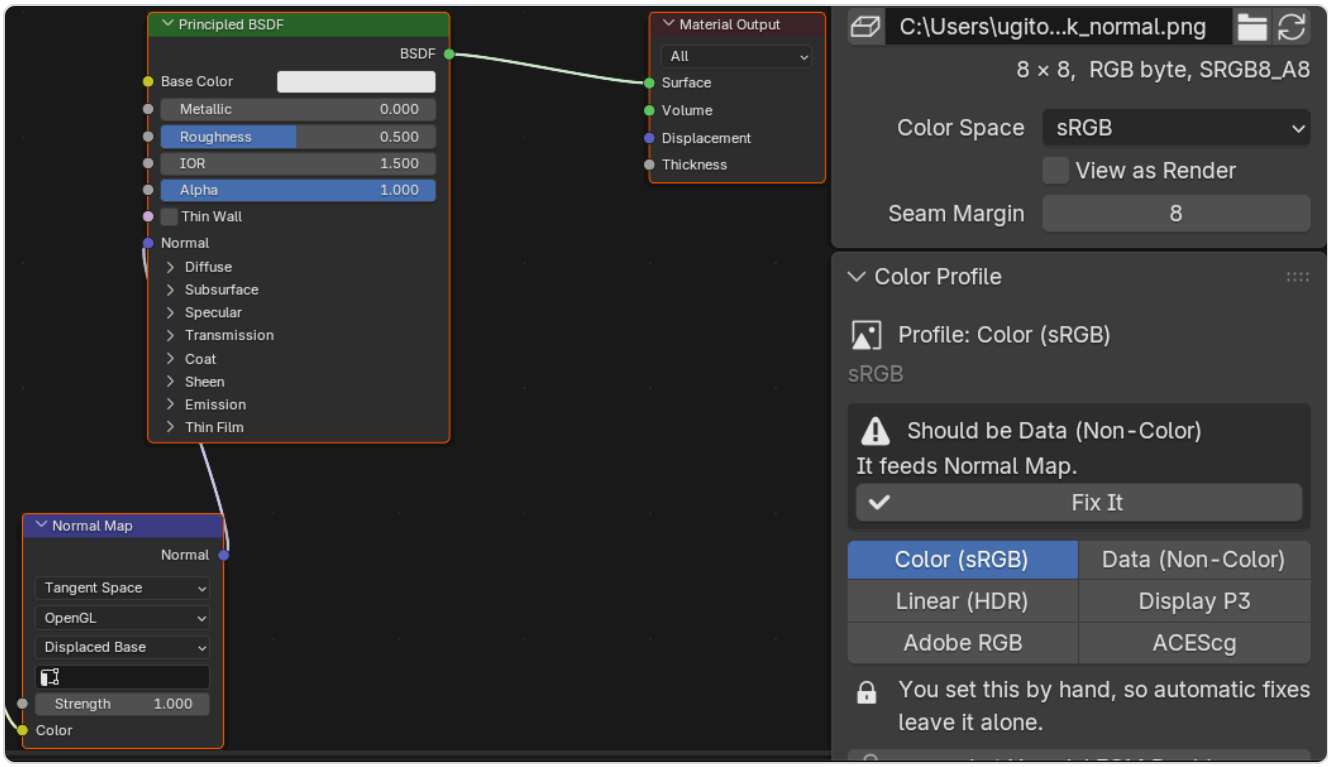

The most common color mistake in Blender is a normal or roughness map left on sRGB. Yasmini ECM follows each image's **Color** output through reroutes, node groups and converter nodes (Separate Color, Math, Color Ramp…) to see what it actually feeds:

- **Base Color, Emission, world background** → Color (sRGB); EXR and HDR files → Linear
- **Normal Map, Bump, Displacement, Roughness, Metallic, Alpha…** → Data (Non-Color)

- **Masks** (through a Color Ramp or a Mix factor) → suggested, but never changed without asking
- **Unconnected images** → judged by name (`wood_Normal_4k.png` , `rock_rough.jpg` , `ORM` ...)

Applying a profile fixes the clear cases. **Textures › Review One by One** lists everything else with the reason. With **Fix New Textures Automatically** on (the default), new images get the right color space as soon as you connect them. Yasmini ECM never touches:

- images you set by hand
- images that were already in a file when you opened it (the Health Check flags those instead)
- images painted or baked in Blender, whose pixels a new color space would alter

Node editor panel

Select an Image Texture node (Node tab of the Shader Editor sidebar), or open an image in the Image Editor (Tool tab), to see its profile and assign one Photoshop-style: Color (sRGB), Data (Non-Color), Linear (HDR), Display P3, Adobe RGB (Blender 5.2+) or ACEScg.

Color profiles in saved files

Blender 5 embeds an ICC profile in the PNG, JPEG and TIFF files it saves. Blender 4 doesn't, so a Display P3 render opens in Photoshop or a browser as if it were sRGB and looks dull. On Blender 4, Yasmini ECM tags every saved render (stills and animation frames) with the right profile. **Advanced › Embed Profile in Files...** does the same for files already on disk, like **Edit › Assign Profile** in Photoshop. Only the tag changes; the pixels stay the same.

Preferences

In **Edit › Preferences › Add-ons › Yasmini ECM**:

- **Profile for New Projects**: applied to every new, unsaved file.
- **My Monitor**: leave it on *Same as the Profile* unless your screen shows wide-gamut colors natively (a wide-gamut monitor in its native mode on Windows or Linux). The viewport then uses your monitor while saved files keep the profile's display, through Blender's output color override. On macOS leave it as is: the system already adapts colors to your screen.
- **Fix New Textures Automatically**, **Embed Color Profiles in Renders** (Blender 4), **Show Profile in Status Bar**.

Limits

- Blender can't render straight to Adobe RGB or CMYK. For print, the Print & Photoshop profile gives you a 16-bit sRGB TIFF to convert in Photoshop.
- EXR files always store linear light. The view transform (AgX, ACES…) is not baked into them.
- The HDR profile needs Blender 5 and an HDR display to preview correctly.

Development

```
yasmini_ecm/              the extension (manifest, Python modules)
tests/test_addon.py       headless tests: profiles, textures, live mode, health, ICC tagging
tests/ui_smoke.py         opens Blender, draws every panel and saves screenshots
dist/                     built extension zip
```

Run the tests and rebuild the zip:

```
blender -b --factory-startup --python tests/test_addon.py
```

```
blender --command extension build --source-dir yasmini_ecm --output-dir dist
```
